

1 64 beam splitter optical attenuation

Overview

A 1:64 splitter adds ~18dB of insertion loss, leaving less power for attenuation—so it's only viable for short distances (5–10km). Passive optical splitters distribute a single optical input into multiple outputs in FTTH, ODN, and PON deployments. The choice of split ratio—1×2, 1×4, 1×8, 1×16, 1×32, or 1×64—directly impacts optical power budget, network reach, subscriber density, and long-term expansion capability. With 1 input port and 64 output ports, it is ideal for large-scale optical distribution, where a signal needs to be. Splitter 1:64 based on Planar Waveguide technology where the light is guided through waveguides in a substrate. The waveguides are branched out according to how much the light should be split. This facilitates for physical small splitters up to 1:64. Operative wavelength: 1260 - 1620 nm. R = reflectance, T = transmittance, A = absorptance (ideally zero) When comparing beam splitters, always check whether the specified R/T ratio is for. Beamsplitters are optical components used to split incident light at a designated ratio into two separate beams.
