

Data Splitter

Article Overview

A data splitter is a device or tool that divides a single data source into multiple outputs, either physically via cables or digitally via file processing.

Hardware Data Splitters

USB and data cable splitters allow one data connection to be shared across multiple devices. For example, a USB splitter can connect one USB port to two devices, enabling simultaneous data transfer, though bandwidth may be shared. Ethernet cable splitters work by splitting the wires inside a single CAT5e or CAT6 cable to carry two separate Ethernet signals. This effectively turns one cable into two connections, typically reducing speed from 1000 Mbps to 100 Mbps per line. Some splitters also separate Power over Ethernet (PoE) from data, allowing non-PoE devices to receive power and data separately. Hardware splitters are plug-and-play, inexpensive, and useful for extending network or device connectivity without additional cabling, though they may reduce maximum speed.

Software/Data File Splitters

File splitters are software tools or online services that divide large datasets into smaller, manageable files. For example, CSV or Excel file splitters allow users to upload a large spreadsheet and split it into multiple files with a configurable number of rows per file. These tools preserve headers, maintain column order, and allow batch processing for platforms with import limits or email attachment restrictions. Processing often happens locally in the browser, ensuring privacy and avoiding server uploads. File splitters save time compared to manual copy-paste methods and are...
