

Why is the received optical power of the optical module negative

Overview

Received optical power (RX, dBm): The optical power arriving at the receiver. RX near or below the module's sensitivity limit explains link drops or high error rates. A healthy RX that's much lower than expected usually indicates fiber loss, dirty connectors, or wrong fiber type. Digital Diagnostic Monitoring (DDM) Function Of Optical Modules enables real-time monitoring of module operation and fault location. Even minor deviations—whether too high, too low, or unstable—can impact signal integrity, trigger service alarms, or interrupt traffic on DWDM, OTN, or long-haul optical line systems. Use vendor datasheets for the allowed operating window. " Optical loss is measured in "dB" which is a relative measurement, while absolute optical power is measured in "dBm," which is dB relative to 1mw optical power. We shut down the local SFP, and monitor the received power on opposite SFP. The received power is always -40dBm when we using below modules. GLC-LH-SMD SFP-10G-LR SFP-25G-SR-S QSFP-100G-LR4-S But when we try on GLC-SX-MMD, the received power is. Every optical transceivers module relies on clean, properly connected fiber.
